For release December 27, 1963

ATLANTA, GEORGIA 30333

Vol. 12, No. 51

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED DECEMBER 21, 1963

BOTULISM - Three cases of botulism were reported this week from Pennsylvania. These occurred in a single family; the vehicle implicated was home-canned string beans. (See epidemiological reports.) The total of 44 cases recorded thus far this year considerably exceeds that of recent years:

Twenty-two of this year's reported cases relate to commercially processed and distributed food stuffs, including smoked whitefish chubs (17 cases), canned tuna (3 cases), and canned liver paste (2 cases).

MENINGOCOCCAL INFECTIONS - Thirty-nine meningococcal infections were reported by 18 States for the week ending December 21. This raises the cumulative total to 2,251 cases thus far this year, compared to 2,048 cases for a comparable period last year.

The net increase of approximately 200 cases this year occurred entirely during the first half of the year. Since July, the incidence has been essentially the same as that observed during 1962.

Total cases to date this year and total cases over the past five years are shown below:

1963 1962 1961 1960 1959 1958

Reported Meningococcol Infections 2251* 2150 2232 2259 2180 2581

EPIDEMIOLOGICAL REPORTS

Botulism - Pennsylvonio

An outbreak of Type B botulism in a Dauphin County, Pennsylvania, family occurred in November following the ingestion of uncooked, home-canned, cold-pack string beans. Of four family members, three developed definite clinical symptoms, one experienced equivocal illness.

The first to become ill was the 13-year-old son who experienced some difficulty with vision approximately 20 hours after consuming the suspect beans at the noon meal on Sunday, November 24. He stated that he experienced a "flash" when he turned his head suddenly. On Tuesday morning, he vomited after breakfast and later in the day noted double vision, "thickness" in his voice and had some difficulty eating. By the third day, he had developed obvious ptosis of the right eyelid; when he attempted to drink, he choked and water came out of his nose.

The 12-year-old daughter experienced nausea and vomiting on the Monday evening following the meal and on the following day stated that her eyes "felt dizzy". By Wednesday, she had evident diplopia, hoarseness and difficulty swallowing.

The mother, aged 32, first experienced double vision and hoarseness on Wednesday.

All three patients were hospitalized, tracheostomy was performed on the children; all received antitoxin at approximately four-hour intervals beginning about 1:00 A.M., Thursday, November 28. All recovered uneventfully.

The father who had eaten no beans complained of numbness in his jaw and stiffness of his throat on Friday, November 29, five days after the meal. This was ascribed simply to anxiety. However, the following day, he commenced to have some difficulty with his vision. Following antitoxin therapy, the symptoms abated. On further questioning, however, it was learned that the father had originally been served the beans but had scraped them from his plate. He did consume the residual juice.

The rapidity of onset of neurological symptoms appeared to correlate reasonably closely with the quantity of beans consumed:

Potient	Age	Quontity Consumed	Intervol - eoting to onset of neuro, symptoms
Son	12	1 cup	30 hours
Doughter	13	2/3 cup	48 hours
Mother	32	1/3 cup	60 hours
Fother		juice only	120-144 hours

Canned by a relative, the beans had originally been cooked and, while still hot, put in clean, boiled two-quart jars and sealed. Received by the family two weeks before eating, the jar was opened, resealed, and stored in the refrigerator. The beans, without further cooking, were

served in a salad. An unpleasant, spoiled odor was noted but discounted as usual with "salted beans" with which the mother had been familiar in Germany.

The uneaten portion of the beans was examined in the State Health Department Laboratory. Type B toxin was demonstrated in the jar and Clostridium botulinum cultured from the beans.

(Reported by Drs. William S. Gordon and D. L. Minter, Harrisburg, Dr. Robert Roscoe, New Cumberland, and Dr. William S. Schrack, Director, Division of Communicable Diseases, Pennsylvania Department of Health.)

Dengue Fever - Connecticut

A case of dengue fever has been reported in a 28year-old male resident of Puerto Rico who visited Connecticut. The patient lived at the outskirts of San Juan.

He arrived from Puerto Rico August 29 to visit his mother in Hamden, Connecticut. Three days later, he became ill with symptoms which included pain in his eyeballs, chest, back, and abdomen, generalized weakness, vomiting, and a fever to 104°. On September 4, a morbilliform rash was noted on his face, arms, chest, and back.

Laboratory studies revealed a trace of albumen in his urine, negative blood cultures, and hemagglutination tests as follows:

Hemogglutination				Dengue				
Inhibition	SLE	EEE	WEE	ı	11	Ш	IV	
9-4-63	<10	<10	<10	<10	<10	<10	<10	
9-10-63	10	<10	<10	10	20	40	40	

The patient recovered uneventfully and returned to Puerto Rico on September 12.

Connecticut officials reported this patient as a case of dengue fever after the hemagglutination tests were received in mid-November.

(Reported by Robert Jordan, M.D.; Leonard Parente, M.D., Director of Health, Hamden; James C. Hart, M.D., Director of Preventable Diseases Section, Connecticut State Department of Health; and Dr. Philip H. Coleman, Chief, Virology Laboratory, CDC.)

Editor's Note: This is the 18th imported case of clinical dengue fever reported to the Communicable Disease Center thus far in 1963. All Victims are believed to have acquired the disease while in either Jamaica or Puerto Rico, where there have been epidemics of denguelike illness. For previous reports, see MMWR, Vol. 12, pp. 270, 308, 310, 378, and 403.

Salmanellosis - Nebraska

Three weeks after an Omaha father acquired "Boots", a pet puppy dog for his two children, the entire family of four experienced diarrhea. The youngest, a 2-year-old, became ill with bloody diarrhea, vomiting, and fever. Stool cultures from the 2-year-old, as well as from the puppy, yielded Salmonella typhimurium.

"Boots" had never been ill to the knowledge of the family. One of 9 in a litter, he had been acquired by his new owner when this puppy, along with its litter mates, was distributed to the patrons of a neighborhood tavem. Attempts to locate the other 8 puppies and their masters for further epidemiological study were unsuccessful because no one could remember the recipients.

All known victims have recovered, following antibiotic therapy. "Boots" was also treated with a broad spectrum antibiotic. Subsequent cultures have proven negative.

(Reported by Dr. E. A. Rogers, Director of Health, Nebraska State Department of Health, Dr. Edwin D. Lyman, Health Officer, Douglas County Health Department, Omaha, Nebraska, and an EIS Officer.)

Solmonellasis - Ohio

A case of gastroenteritis due to Salmonella typhimurium in a 3-month-old Cincinnati, Ohio, infant appears to have been acquired from a pet parakeet, which died 4 days prior to the onset of the baby's symptoms.

The child had experienced diarrhea. A stool culture grew S. typhimurium. The same organism was isolated from the stools of 2 siblings, who were not ill.

On interviewing the family, the investigators from the Cincinnati Health Department learned of the parakeet's death. The deceased parakeet was no longer available for culture. Therefore, the investigator visited the pet store where the bird had been purchased. There had been no illness among the personnel caring for the parakeets nor had there been a history of any parakeets having been ill or having died while at the shop. Cultures of droppings were taken from parakeets present in the store at that time. These proved positive for S. typhimurium.

Investigators could not find evidence of salmonellosis in the birds at the distributing center, or at any of the other stores which received parakeets from the same distributor.

Because the birds had been fed dehulled millet seed, impregnated with aureomycin, for 15 days prior to their shipment, Ohio investigators believed the source of contamination was local where antibiotic was not added to the seed. They surmised that the local parakeet seed might have been contaminated with mouse droppings. (Reported by Dr. Thomas A. Cockburn, Assistant Health Commissioner, Cincinnati Board of Health, Dr. Herman Rebder, Veterinarian, Cincinnati Board of Health, and Dr. Harold A. Decker, Chief, Division of Communicable Diseases, Ohio State Department of Health.)

INFANT DEATHS IN 108 CITIES

The weekly average number of infant deaths in 108 cities for the four-week period ending December 21 was 738 as compared with an expected 769 weekly average.

Dengue - Puerto Rico

For the week ended December 21, 783 cases of dengue-like illness were reported to the Puerto Rico Department of Health. The total reported to date is 24,933 cases.

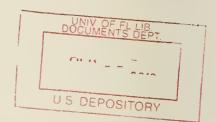

On the basis of reported cases, no evident trend can yet be detected in the course of the epidemic. Reported numbers of cases by week for November and December are shown below:

No. of Cases
962
916
1733
473
1011
1278
783

(Reported by Rafael Timothee, M.D., Director, Preventive Medical Services, Puerto Rico Department of Health, and a team from the Communicable Disease Center.)

In addition to the established procedures for reporting morbidity and mortality, the Communicable Disease Center welcomes accounts of interesting outbreaks or cases. Such accounts should be addressed to:
